Анализ количества точек в полигонах

Мощь ГИС заключается в совместном анализе нескольких источников данных. Зачастую, ответ, который вы ищете, лежит в разных слоях, и вы должны произвести какой-то анализ, чтобы извлечь и обобщить данную информацию. Одним из таких видов анализа является Points-in-Polygon. Если у вас есть полигональный слой и точечный слой, и вы хотите знать, как много или какие именно точки попадают в каждый полигон, вы можете использовать этот метод анализа.

Обзор задачи

Учитывая расположение всех известных значимых землетрясений, мы постараемся выяснить, в какой стране было больше всего землетрясений.

Получение данных

We will use NOAA's National Geophysical Data Center's [Significant Earthquake Database](#) as our layer representing all major earthquakes. Download the [tab-delimited earthquake data](#).

Natural Earth has [Admin 0 - Countries](#) dataset. Download the [countries](#)

Источники данных: [NGDC] [NATURALEARTH]

Методика

1. Open Layer > Add Delimited Text Layer and browse to the downloaded **signif.txt** file.

2. Since this is a tab-delimited file, choose Tab as the File format. The X field and Y field would be auto-populated. Click OK.

Note

You may see some error messages as QGIS tries to import the file. These are valid errors and some rows from the file will not be imported. You can ignore the errors for the purpose of this tutorial.

Create a Layer from a Delimited Text File

File Name:

Layer name: Encoding:

File format: ☐ CSV (comma separated values) ☒ Custom delimiters ☐ Regular expression delimiter

☐ Comma ☒ Tab ☐ Space ☐ Colon ☐ Semicolon

Other delimiters: Quote: Escape:

Record options: Number of header lines to discard: ☒ First record has field names

Field options: ☐ Trim fields ☐ Discard empty fields ☐ Decimal separator is comma

Geometry definition: ☒ Point coordinates ☐ Well known text (WKT) ☐ No geometry (attribute only table)

X field: Y field: ☐ DMS coordinates

Layer settings: ☒ Use spatial index ☐ Use subset index ☐ Watch file

	I_D	FLAG_TSUNAMI	YEAR	MONTH	DAY	HOUR	MINUTE	SECOND	FOCAL_DEPTH	EQ_MAG_MW	EQ_MAG
1	1		-2150								
2	2	Tsu	-2000								
3	3		-2000						18		7.1
4	8		-1566								
5	11		-1450								

3. As the earthquake dataset has Latitude/Longitude coordinates, choose WGS 84 EPSG:4326 as the CRS in the Coordinate Reference System Selector dialog.

4. The earthquake point layer would now be loaded and displayed in QGIS. Let's also open the Countries layer. Go to Layer > Add Vector Layer. Browse to the downloaded *ne_10m_admin_0_countries.zip* file and click Open. Select the *ne_10m_admin_0_countries.shp* as the layer in the Select layers to add... dialog.

5. Click on Vector › Analysis Tools › Point in Polygon

6. In the pop-up window, select the polygon layer and point layer respectively. Name the output layer as ***earthquake_per_country.shp*** and Click OK.

Note

Be patient after clicking OK, QGIS may take upto 10 minutes to calculate the results.

7. When asked whether you want to add the layer to TOC, click Yes.

8. You will see a new layer is added to the table of content. Open the attribute table by right-clicking on the layer and selecting Open Attribute Table.

9. In the attribute table, you will notice a new field named *PNTCNT*. This is the count of number of points from the earthquakes layer that fall within each polygon.

Attribute table - earthquakes_per_country :: Features total: 255, filtered: 255, selected: 0

10. To get our answer, we can simply sort the table by *PNTCNT* field and the country with highest count will be our answer. Click 2-times on the *PNTCNT* column to get it sorted in descending order. Click on the first row to select it and close the Attribute Table.

We determined from the simple analysis of 2 datasets that China has had the highest number of major earthquakes. You may refine this analysis further by taking into consideration the population as well as the size of the country and determine which is the most adversely affected country by major earthquakes.
